Microservices & Kafka

Streaming | Messaging platform

Popular with Microservices developers

Microservices & Kafka

Overlapping of capabilities

Microservices & Kafka

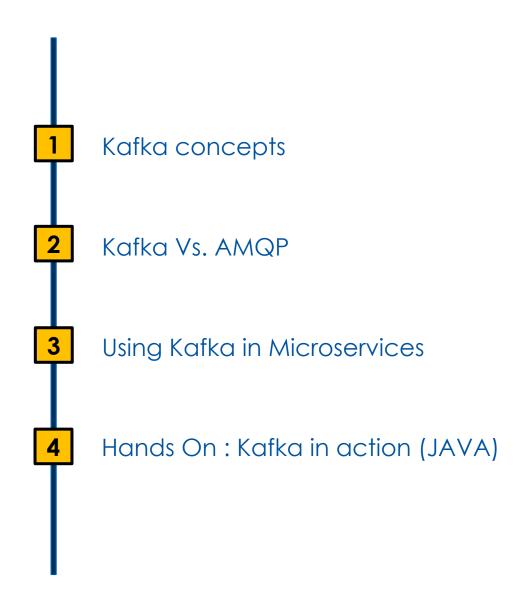

Which one should be used for Microservices?

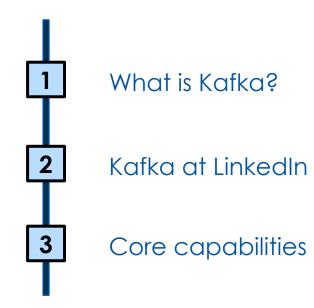

Kafka 101

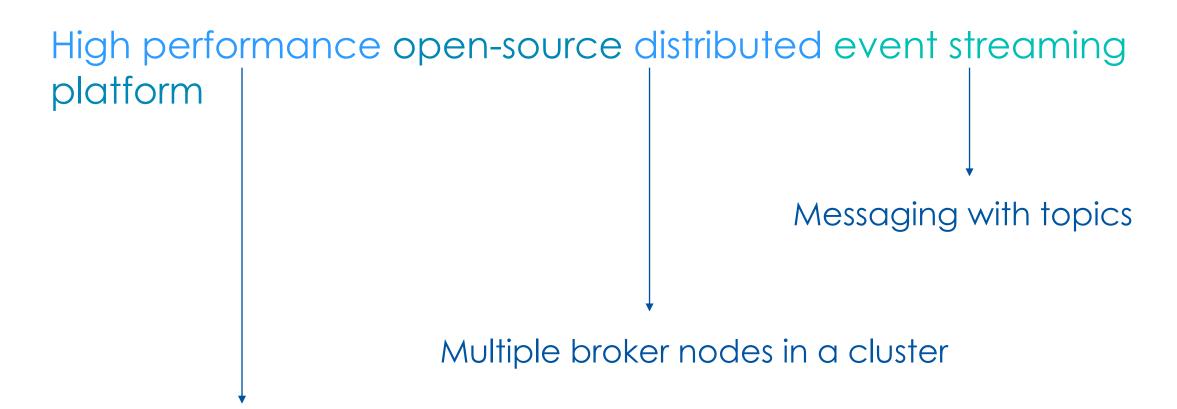

A quick introduction to Kafka

Kafka

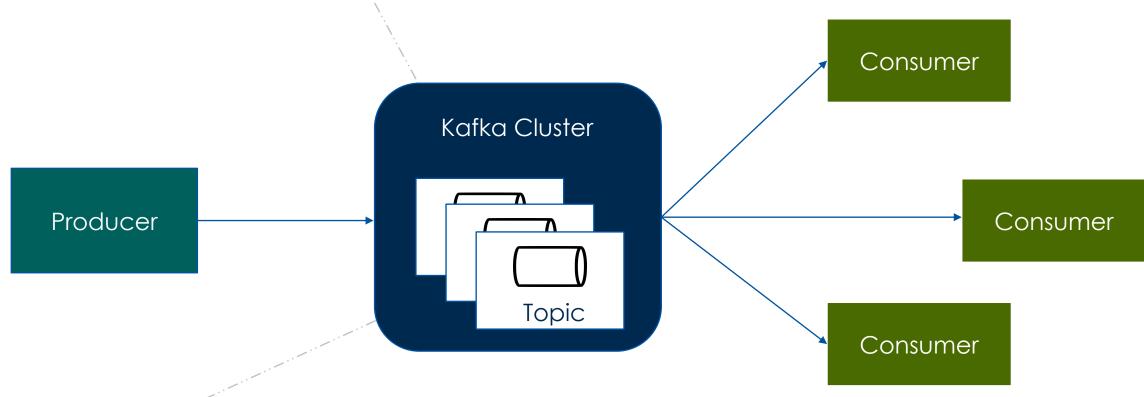

2 Million writes/second

Kafka = Distributed messaging system

May consist of 1000's of machines across a network

May consist of 1000's of topics

Data persisted & replicated across thousands of partitions

Built for scale

Developed at Linked In & open sourced in 2011

• 7 Trillion messages / day

100 Clusters

4000 Brokers

• 100,000 Topics

7,000,000 Partitions

Core capabilities

HIGH THROUGHPUT

Deliver messages at network limited throughput using a cluster of machines with latencies as low as 2ms.

Scale production clusters up to a thousand brokers, trillions of messages per day, petabytes of data, hundreds of thousands of partitions. Elastically expand and contract storage and processing.

PERMANENT STORAGE

Store streams of data safely in a distributed, durable, fault-tolerant cluster.

HIGH AVAILABILITY

Stretch clusters efficiently over availability zones or connect separate clusters across geographic regions.

Kafka is a highly scalable & distributed messaging platform

Microservices use cases for Kafka

Kafka vs AMQP

Hands on experience with Kafka

Kafka Concepts

Ecosystem

BUILT-IN STREAM PROCESSING

Process streams of events with joins, aggregations, filters, transformations, and more, using event-time and exactly-once processing.

CONNECT TO ALMOST ANYTHING

Kafka's out-of-the-box Connect interface integrates with hundreds of event sources and event sinks including Postgres, JMS, Elasticsearch, AWS S3, and more.

CLIENT LIBRARIES

Read, write, and process streams of events in a vast array of programming languages.

OPEN SOURCE TOOLS

Large ecosystem of open source tools: Leverage a vast array of community-driven tooling.

Kafka Concepts

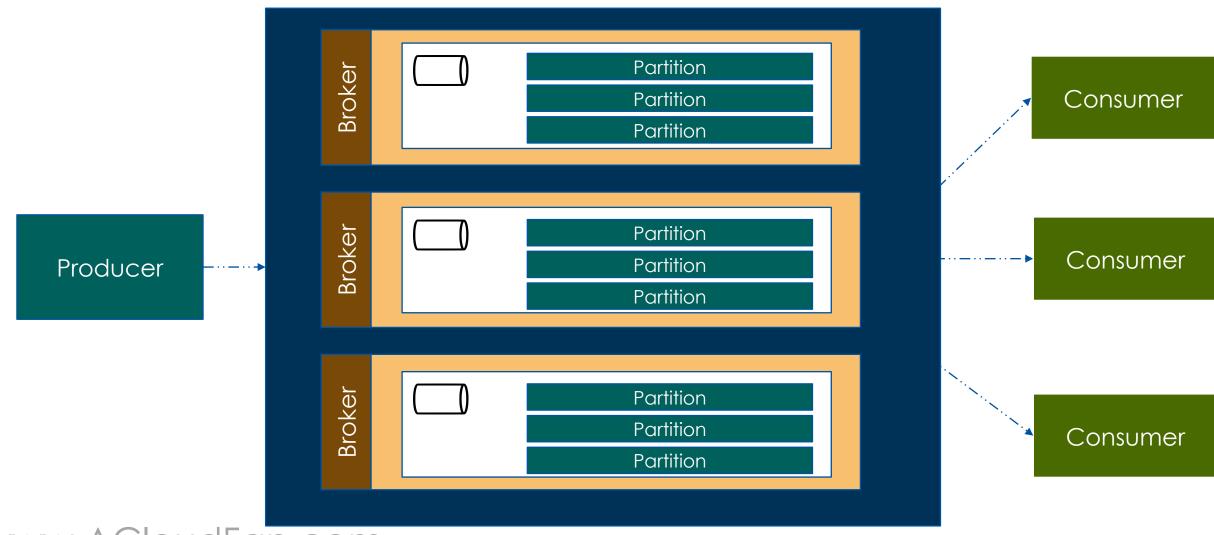

Common terms used in Kafka

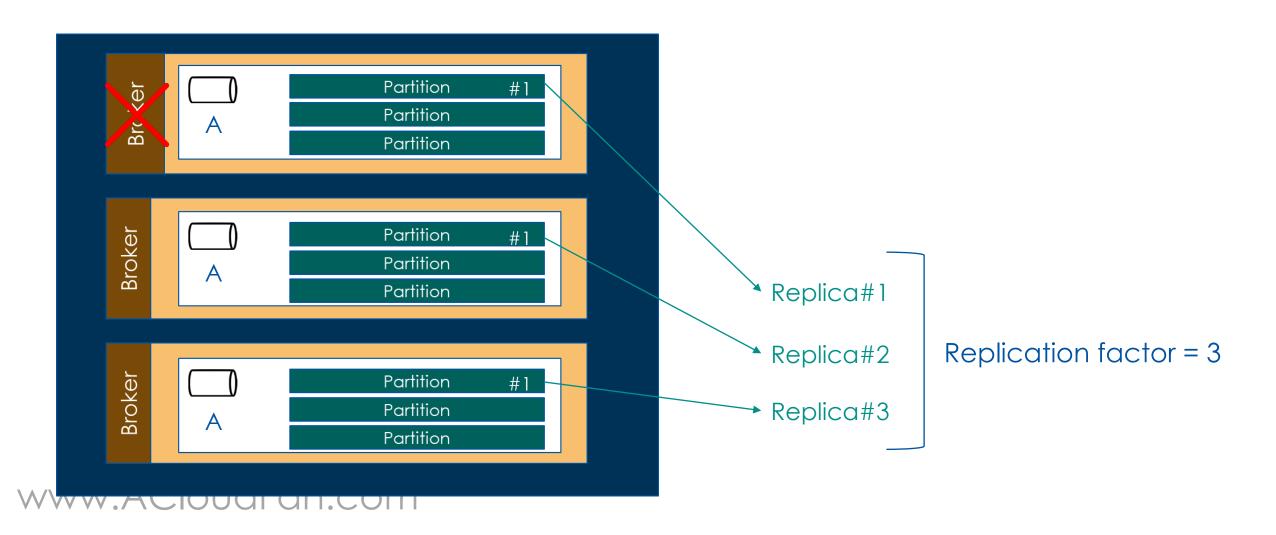

Kafka Cluster

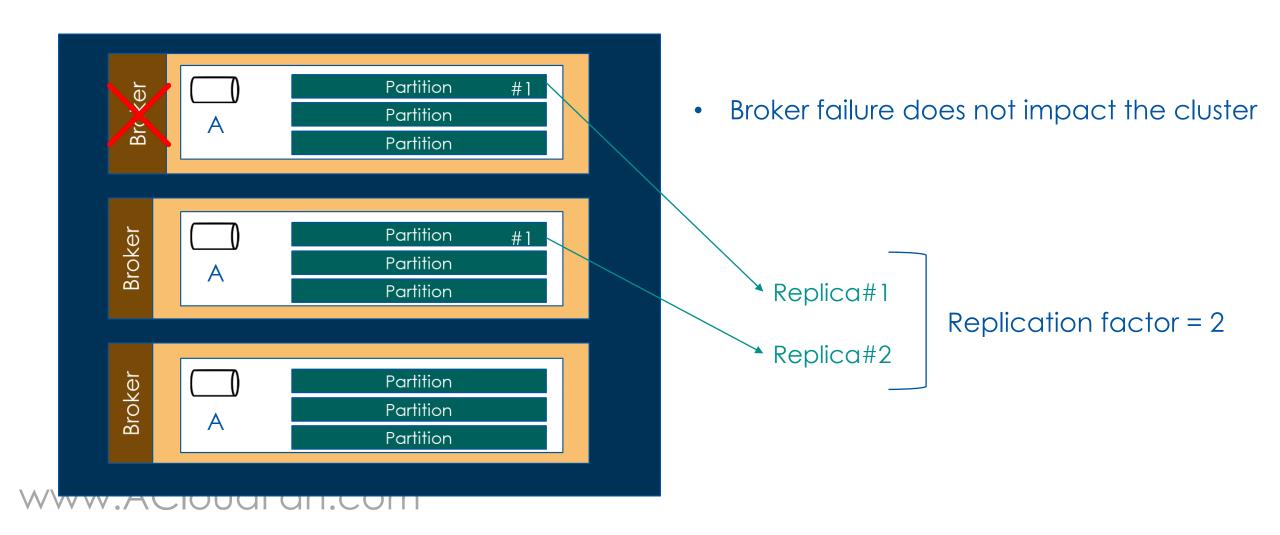

Event Message data

Replicated across multiple Brokers in the partitions

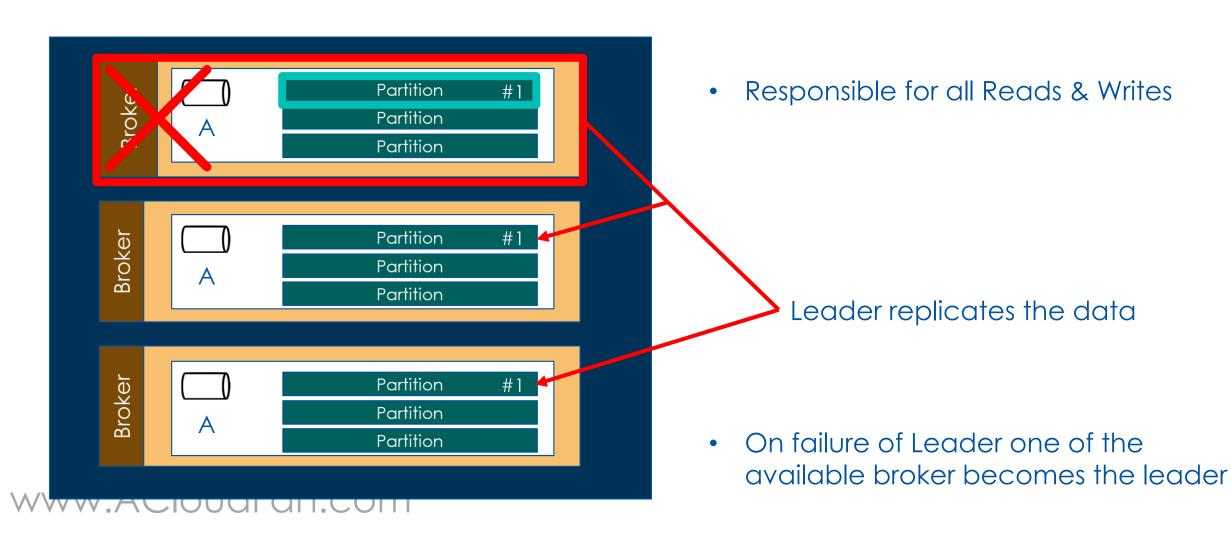

Event Message data

Replicated across multiple Brokers in the partitions

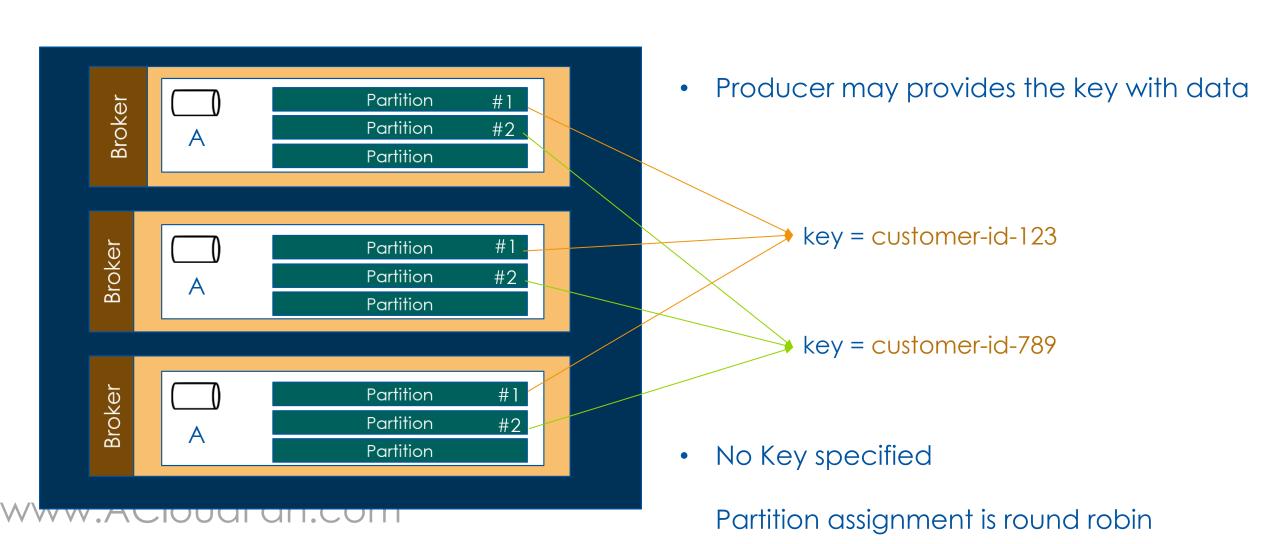

Leader

One node act as a Leader for a partition

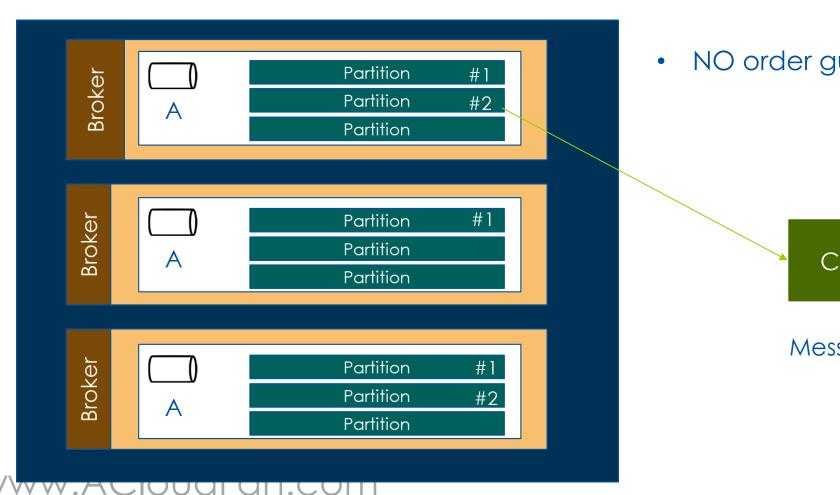

Partitions

Message Data is partitioned on message key

Message Ordering

Messages are ordered ONLY within a partition

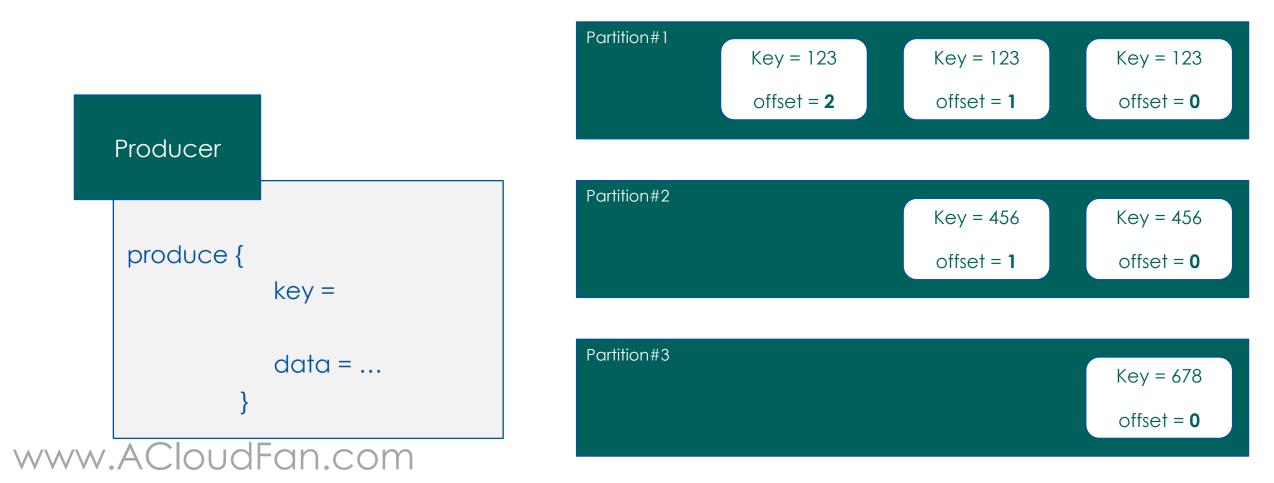

NO order guarantee across partitions

Consumer

Message order maintained

Producer | Publishing

Each message in a partition is assigned an offset

Consumer polls for the messages; fixed interval

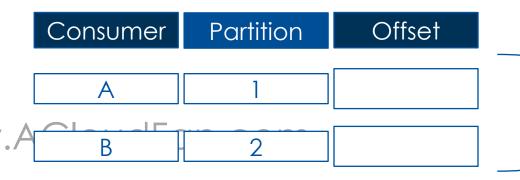

Acknowledges the message after read

Unlike AMQP - Message is <u>NOT</u> removed

Kafka updates read offset for that consumer

Maximum of 1 active consumer per partition

Kafka maintains the current position of the consumer to avoid duplication

Reads are NON-destructive

Consumer can Reset the offset

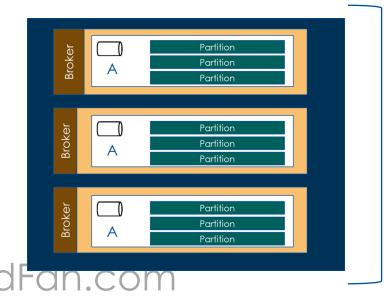

Consumer can replay the log/messages from any offset

Messages expire after the retention period

Consumer may manage the offset on it's end instead of relying on Kafka

Multiple consumer instances can listen to a common topic

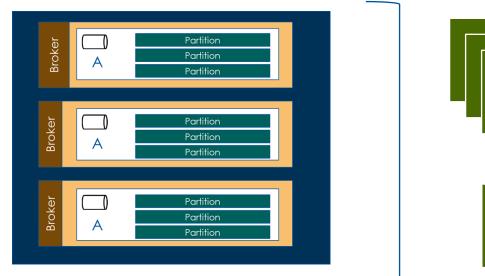

- Each message to be received by ONLY one consumer in the group
 - Such consumers are grouped by way of group ID

Common group ID assigned to each consumer

Max number of consumer in a group = Number of partitions

Max of 3 consumers in a Group

Reads are nondestructive

Topics have partitions; message key determines the partition

Kafka manages the offset; consumer can reset offset

Consumers can read as a group by way of group ID

Kafka cluster setup

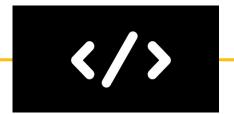

Setup a Kafka cluster on the cloud

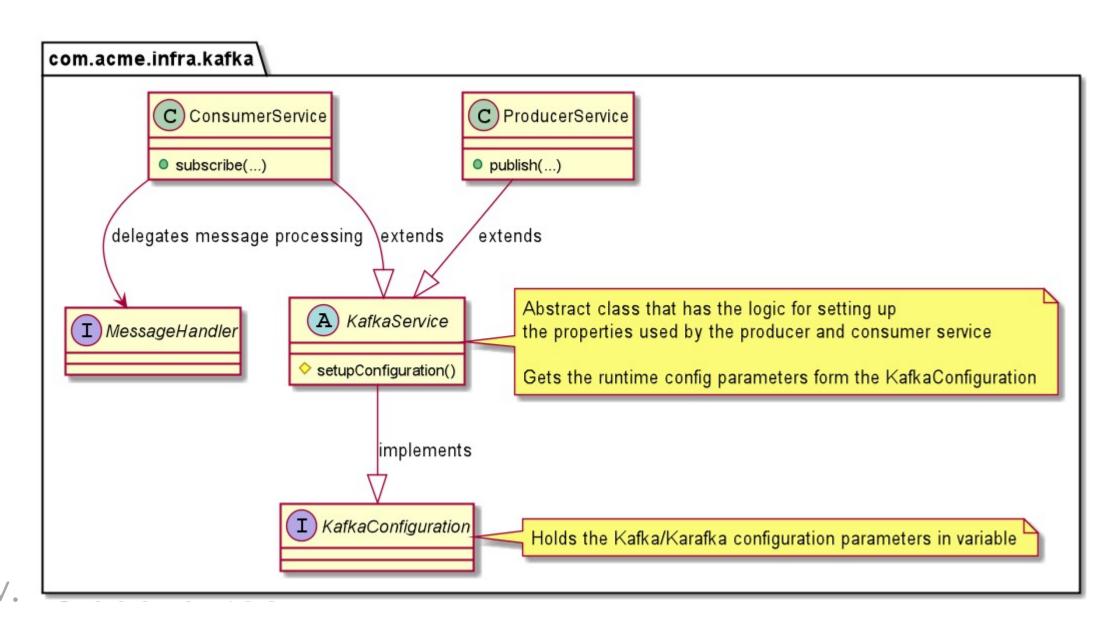

Kafka producer in action

Publish messages to Kafka topic

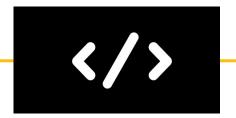

Kafka consumer group in action

Receive messages in a consumer group

Kafka Rebalancing Protocol

ONE consumer per partition

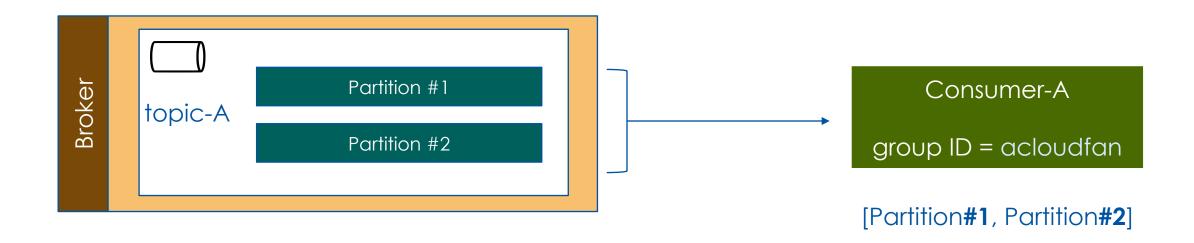

Kafka ensures that:

Each consumer in a groups attach to 0 or more partitions

Consumer group automatically re-assign partitions

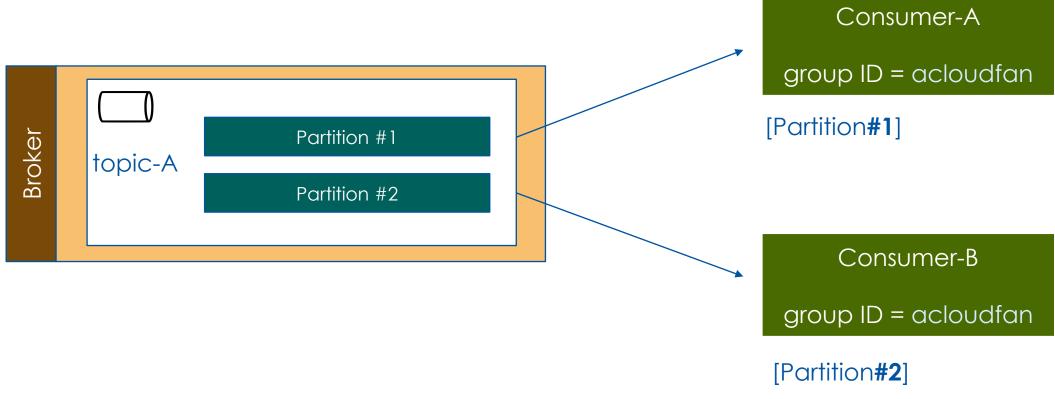

Consumer Rebalancing

Kafka consumers in a group are automatically re-balanced

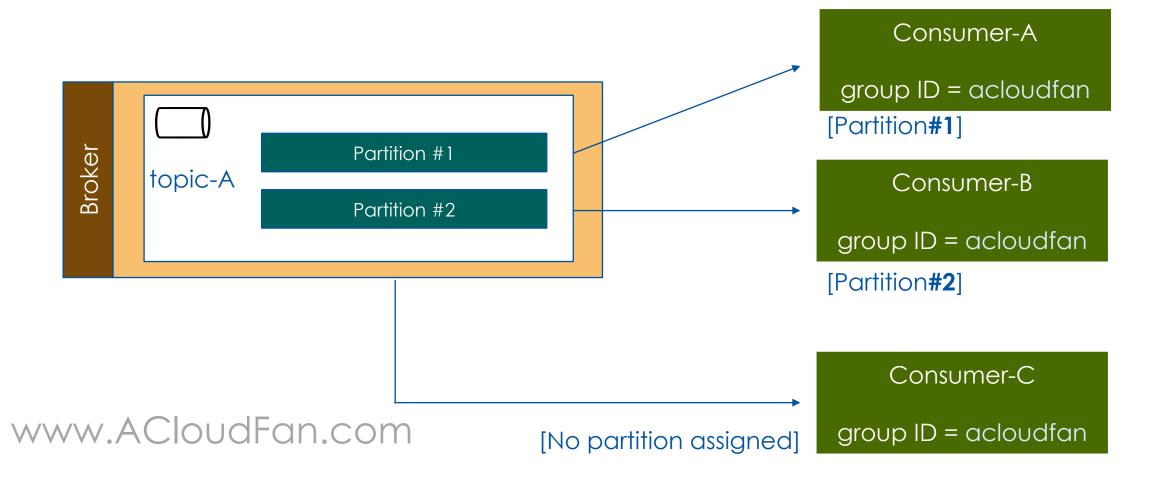

Consumer Rebalancing

Kafka consumers are reconfigured automatically

Consumer Rebalancing

Consumer placed in wait state if number of consumers exceed number of partitions

Testing steps: Kafka rebalancing

Create a new topic with 2 partitions

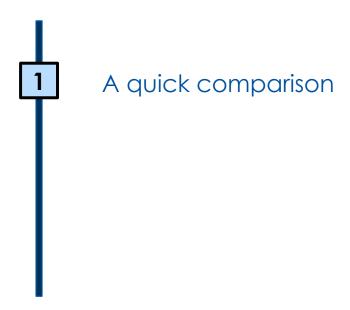

2 Setup 2 consumer/subscriber instances

3 Publish messages with different keys

Kafka versus AMQP

Differences between the messaging platforms

LRabbitMQ

What would you use for Microservices?

Kafka always persists the message

Message automatically expires after the set duration

Messages are not removed on READ so can be replayed

Kafka uses a custom protocol

Binary protocol over TCP

Protocol used by Kafka is NOT a standard

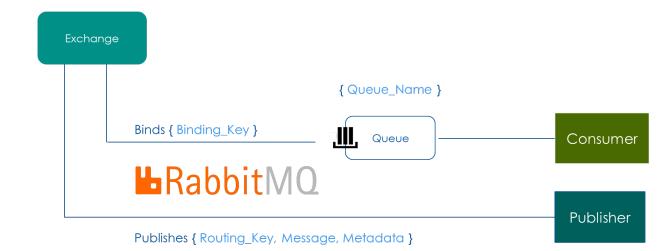

Kafka does not support routing

Dynamic routing is possible but not out of the box

AMQP has a very flexible routing mechanism

Kafka has no concept of Queue

Supports ONLY publish-subscribe messaging pattern

AMQP support point-to-point and publish-subscribe patterns

Kafka consumers ALWAYS pull messages from broker (polling)

Consumer poll for the specific duration & receive batches

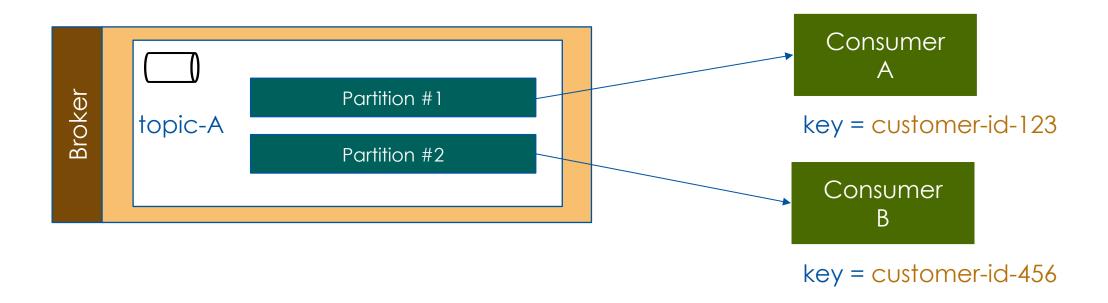

AMQP/RabbitMQ supports push and pull

Kafka does not have the concept of:

• Exchanges, Queues, Bindings

Message priority

Kafka by default guarantees message ordering per partition

Consumer receives messages in order they were published

www.ACloudFan.com

Kafka by default guarantees message ordering per partition

LRabbitMQ

Message in a queue may be read by multiple consumers

Processing order is not guaranteed !!!

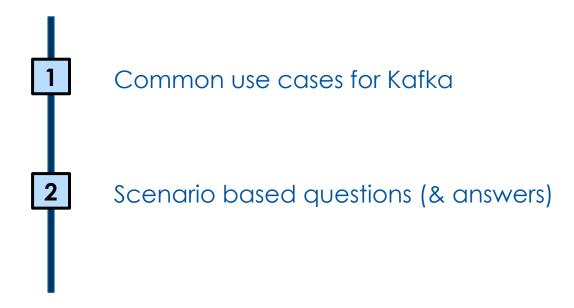

www.ACloudFan.com

- 1. Kafka message reads are nondestructive
- 2. Kafka does not support Queue, Exchange, Routing, Priorities
- 3. Kafka uses a custom binary TCP protocol
- 4. Kafka supports ONLY pub-sub and pull based message receive
- 5. Kafka guarantees message order within a partition

Kafka for Microservices

Messaging for microservices

LRabbitMQ

What would you use for Microservices?

Depends on the use cases for your microservice

What would you use for Microservices?

Large scale messaging applications

Strong message durability

Unlimited scaling by way of topic | partitions

Web site tracking a.k.a. click stream analysis

• Site activity requires high ingestion rate; one topic per activity

This was the original use case for Kafka

Log aggregation & Stream processing

Collection of logs from servers/application across 1000s of servers

Data received as event streams that may be analyzed in Realtime

Event sourcing | Kafka is a natural Event Store

Time ordered sequence of records

Event data is retained in Kafka and may be replayed

Commit Log

Provides commit-log for a distributed system

• Supports replication of data between nodes; re-syncs failed nodes

Question & Answers time!!

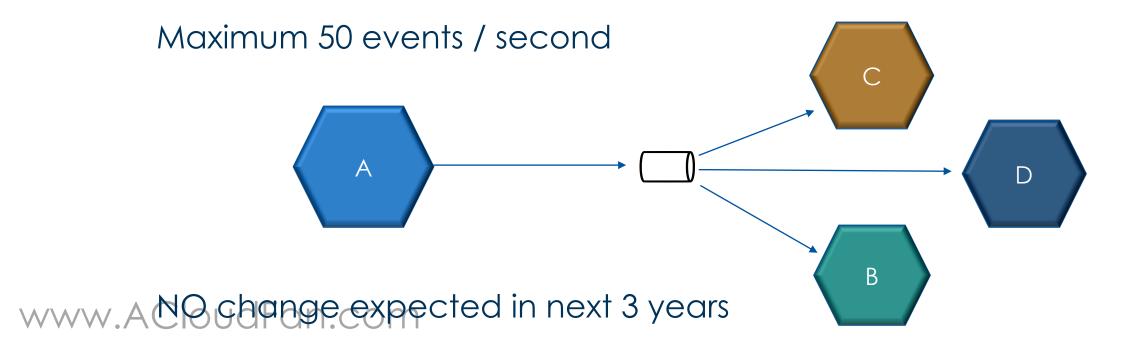

Which one would you prefer & why?

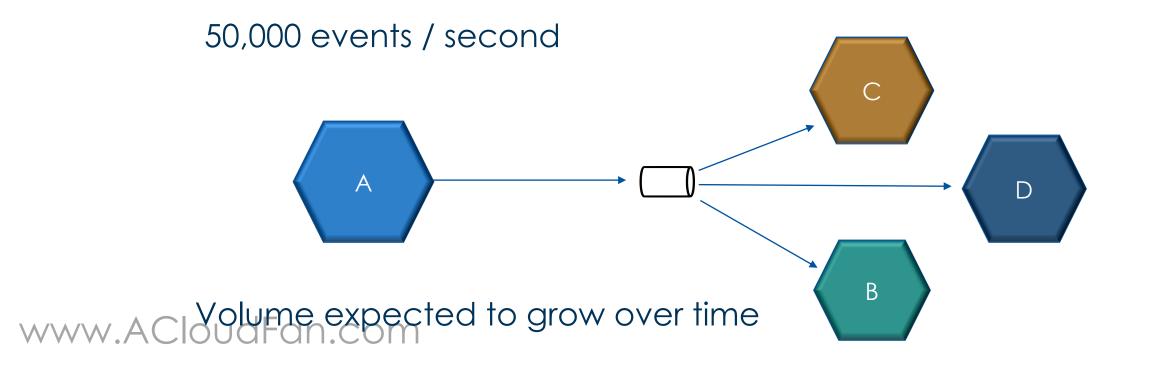

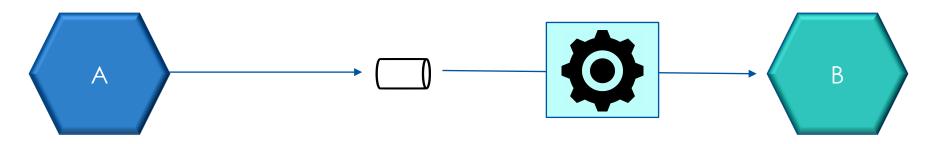

LRabbitMQ

1000 events / second

Real time events analysis

E.g., anomalous credit card charges

Provides a standard based messaging interface

Consumers of the interface prefer simplicity

Assume: Messaging requirements may be fulfilled by both

As a developer I would like to have full control on routing of event data
